# Hydride Earth (HE) model ( primordially Hydrogen-Rich Planet)

was born 50 years ago and does not killed up to now

- Basic idea:

Planet chemical composition depends on distance from the Sun.

Earth chemical composition  $\neq$  Asteroid Belt chemical composition. Larin's law:

$(X_M/X_{Si})_{\text{Earth}} = (X_M/X_{Si})_{\text{Sun}} \cdot F(E_{IP}(M))$ ; where  $X_M$  is the mass fraction in the planet mass of the chemical element with atomic number M,  $E_{IP}(M)$  is the ionization potential of the chemical element with atomic number M

# Hydride Earth (HE)

- There are U, Th, K in Lower mantle and Core
- Mantle → metallic
- External Core →  $\text{FeH}_4 + \text{NiH}_4 + \text{MgH}_4 + \text{NaH}_4 \dots$
- Percentage of K in Earth mass is 2 %– 4 %
- HE model can explain experimentally observed value of Earth heat flux 300 TW.  $^{40}\text{K}$  decay give the main contribution in Earth heat flux. Leonid Bezrukov. Geoneutrino and Hydridic Earth model. Preprint INR 1378/2014. arXiv:1308.4163
- HE model predicts that Earth heat flux is not stationary.

EPJ Web of Conferences **125**, 02004 (2016) DOI:

[10.1051/epjconf/201612502004](https://doi.org/10.1051/epjconf/201612502004)

- **Abstract.**

Experimental data on geoneutrinos allow to admit that masses of U, Th and K in the Earth can be up to  $mU = 1.7 \cdot 10^{17}$  kg,  $mTh = 6.7 \cdot 10^{17}$  kg and  $mK/mEarth \sim 2\%$ . These values correspond to intrinsic Earth heat flux in  $\sim 300$  TW. The most part of this flux goes up in rift zones as a heated gases. Argo Project results and the measurements of the Moon intrinsic heat flux support the existence of such a big flux. So large of U, Th, K abundances were predicted by Adjusted Hydridic Earth model.

# *Conclusion. GeoV. Exp.*

- The fluxes of U and Th GeoV are recorded.  
U and Th BSE concentrations can be changed slightly by putting some U and Th in the Earth mantel and the core → the upper limit

$$H_U + H_{Th} \approx 40 \text{ TW}$$

- There is K GeoV signal

$$2\% \rightarrow H_K = 260 \text{ TW}$$

# Experiment LENS

- Proposed by R. Raghavan
- The target -  $^{115}\text{In}$
- Sensitive to all type solar neutrino
- Not sensitive to  $^{40}\text{K}$  geo antineutrino

# Summary

- 40K geo-antineutrino contribute to Borexino single event according to Hydride Earth model. 2 – 3 events per day.
- The flux of CNO neutrino must be suppressed in this case. The reactions with fast alpha particles can be the reason of such suppression.
- The detector for CNO neutrino must be built.

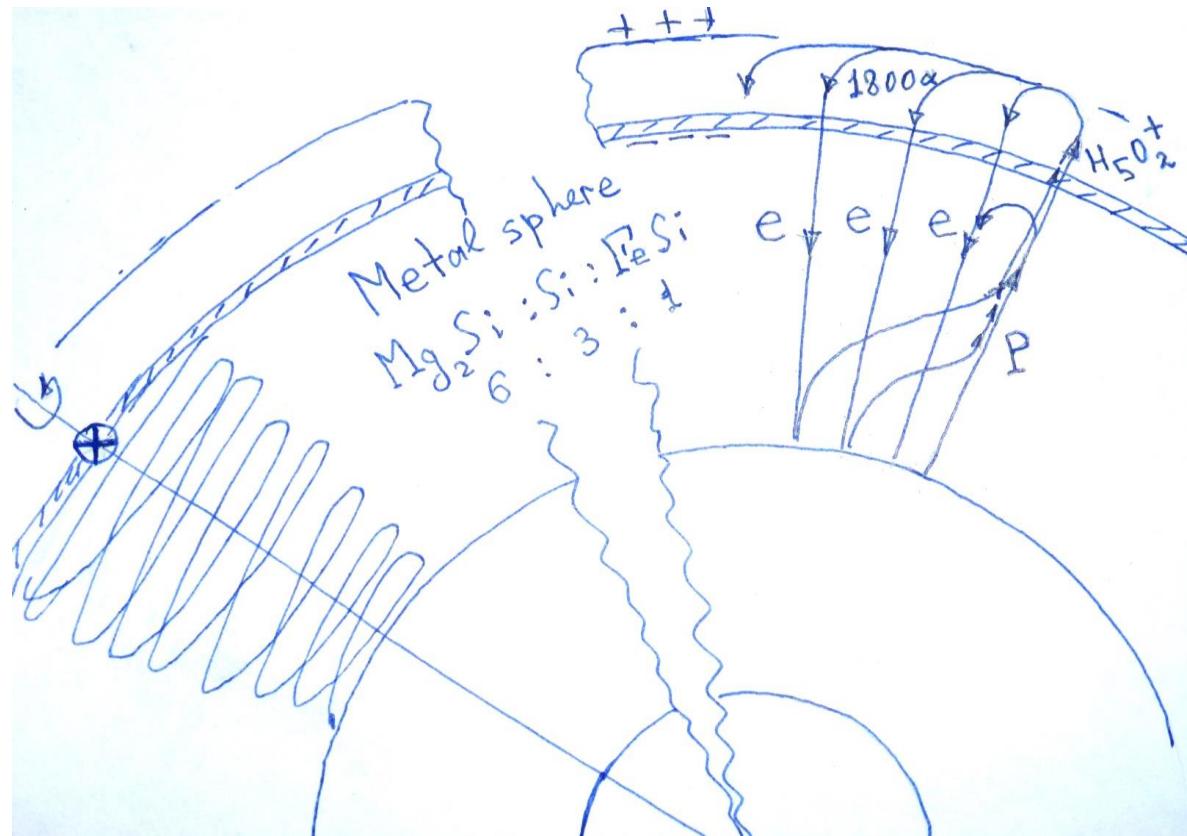

# Hydride Earth (HE)

- There are U, Th, K in Lower mantle and Core
- Mantle → metallic
- External Core →  $\text{FeH}_4 + \text{NiH}_4 + \text{MgH}_4 + \text{NaH}_4 \dots$
- Percentage of K in Earth mass is 2 %– 4 %
- HE model can explain experimentally observed value of Earth heat flux 300 TW.  $^{40}\text{K}$  decay give the main contribution in Earth heat flux. Leonid Bezrukov. Geoneutrino and Hydridic Earth model. Preprint INR 1378/2014. arXiv:1308.4163
- HE model predicts that Earth heat flux is not stationary.

# Verification of Hydride Earth (HE) model

- To prove the HE model we developed the Hydride Earth Electricity (HEE) model
- We prove the HEE experimentally. We observed the unusual predicted fact: The Earth crust (continents and ocean) saturates by positive ions (protons).

# Hydride theory of Earth electricity

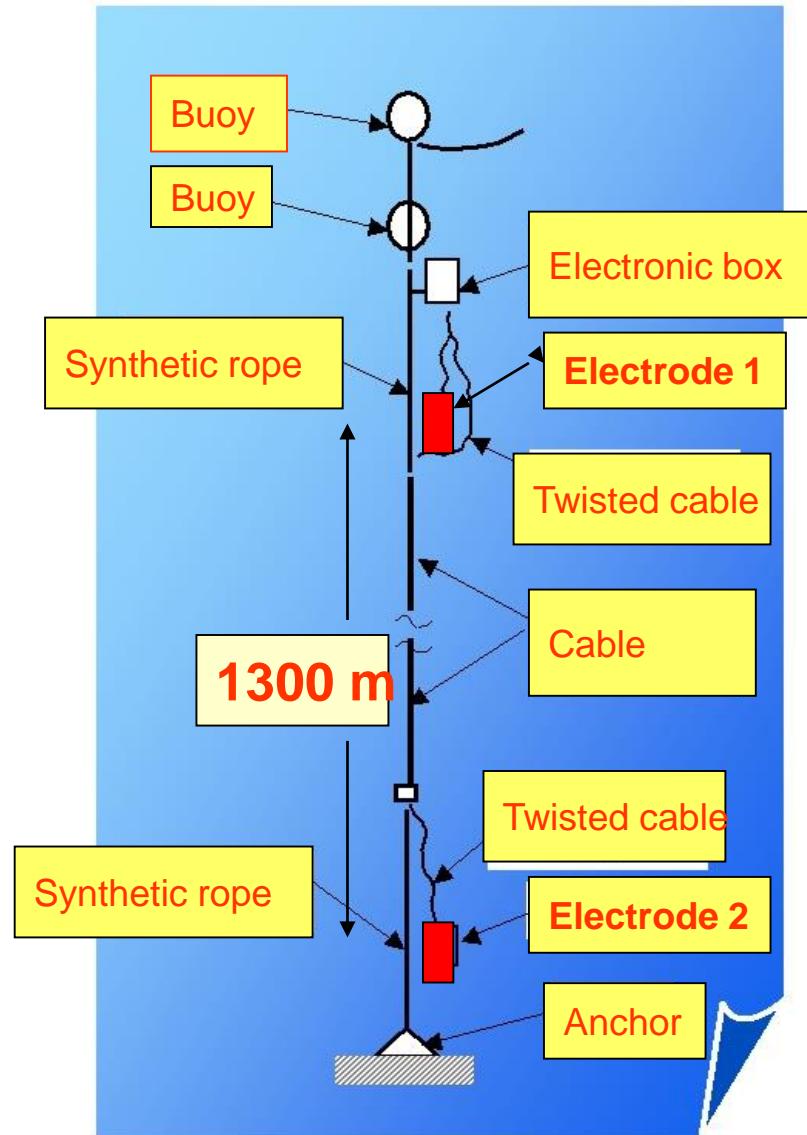

- The negative charge of “Earth capacitor” locates under Earth crust.
- The Earth crust (continents and ocean) saturates by positive ions (protons).
- The gases goes up from the Earth crust to atmosphere mostly by narrow jets. These gases are positive charged and can charge the “Earth capacitor”.

# INR underground lab. Moscow

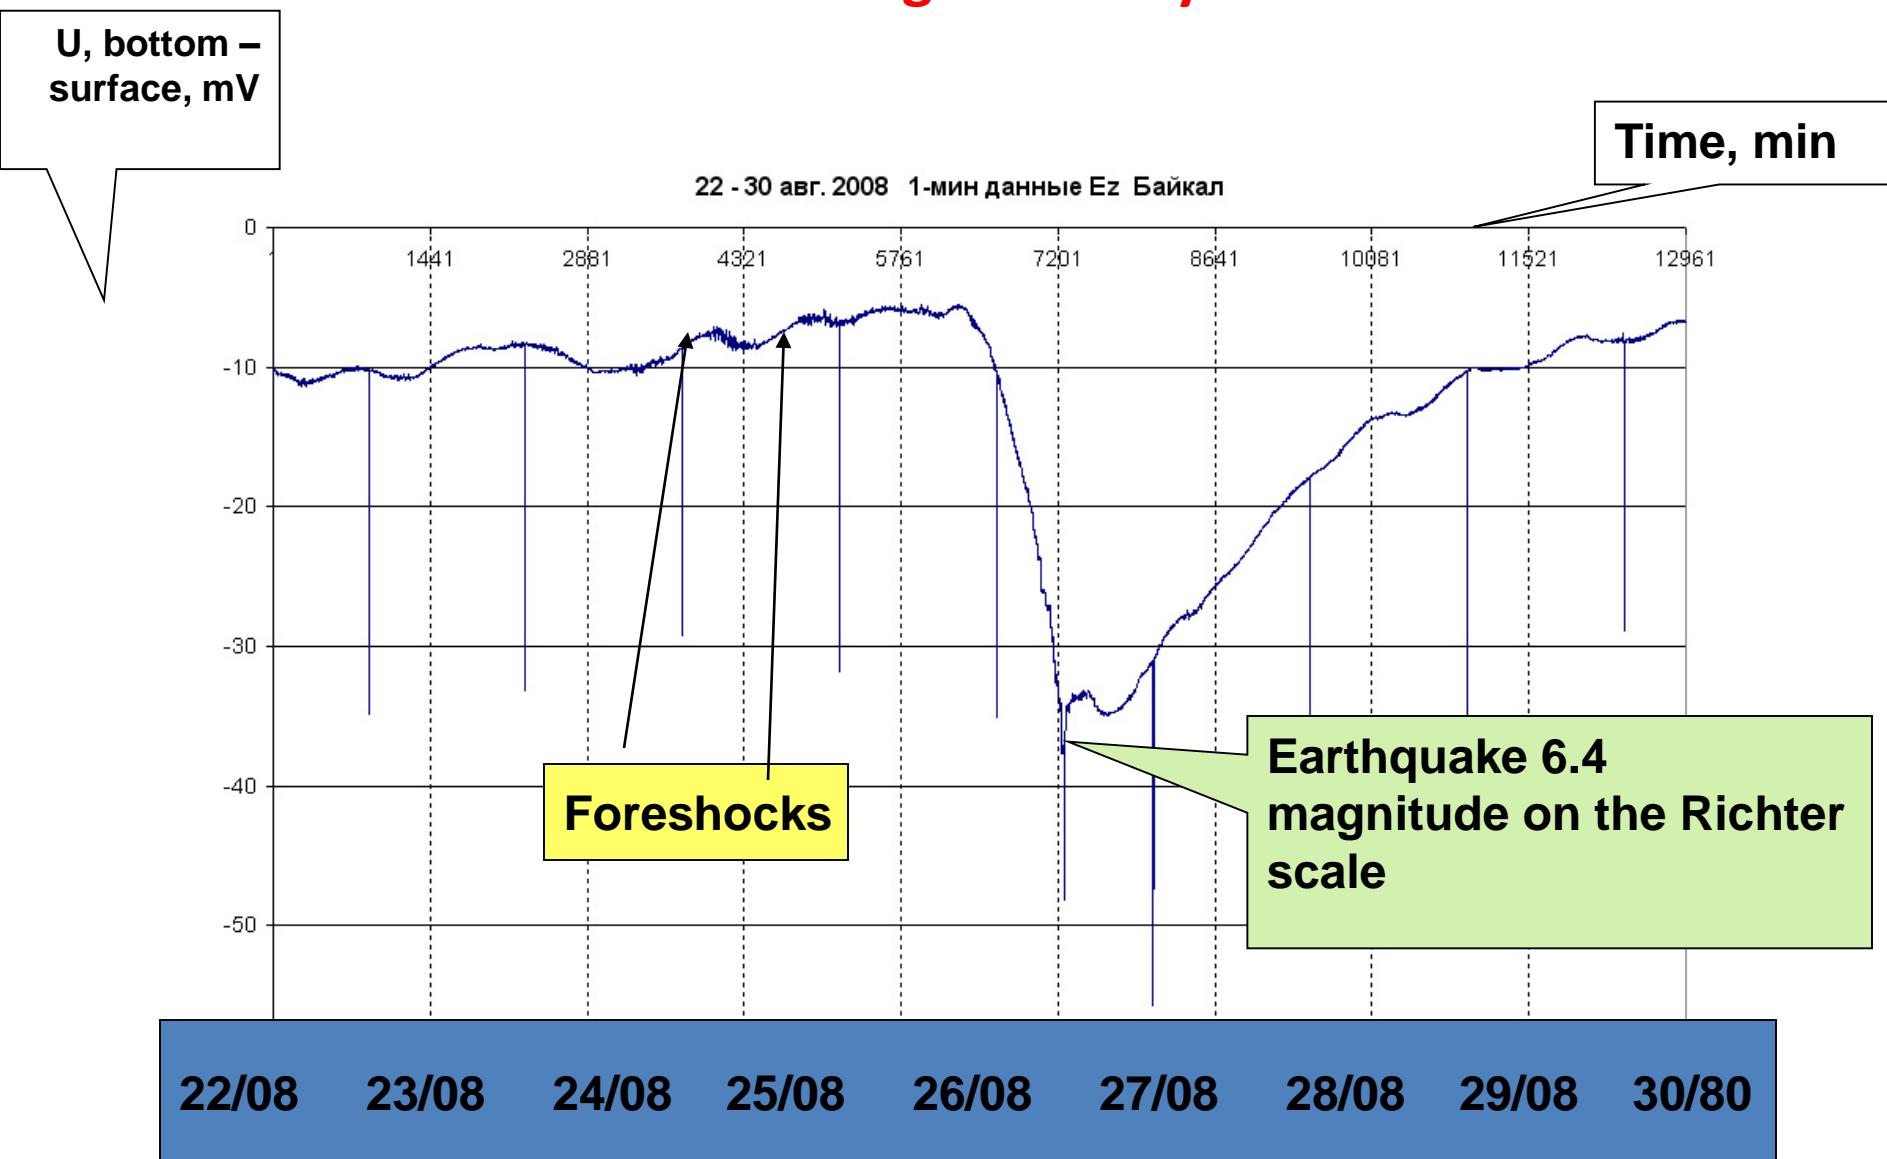

# GEOPHYSICAL STRING

Electrode 2 connects to pluse (+) terminal of voltmeter

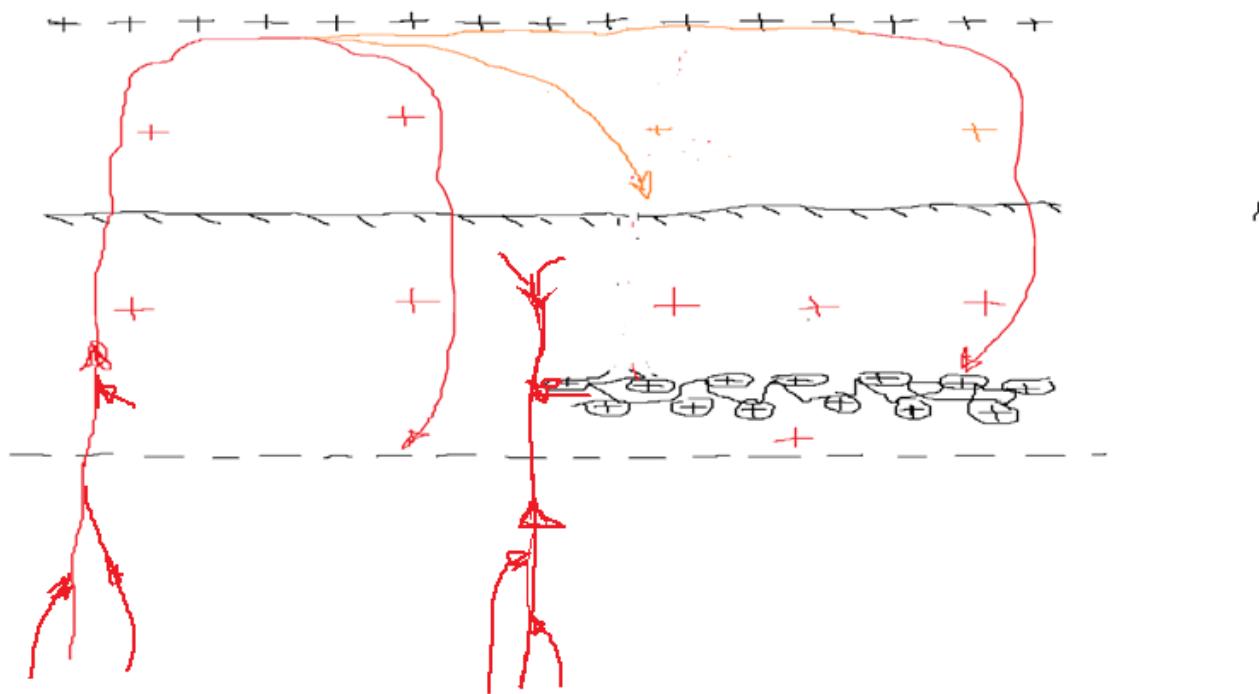

# Surface – bottom electric potential difference

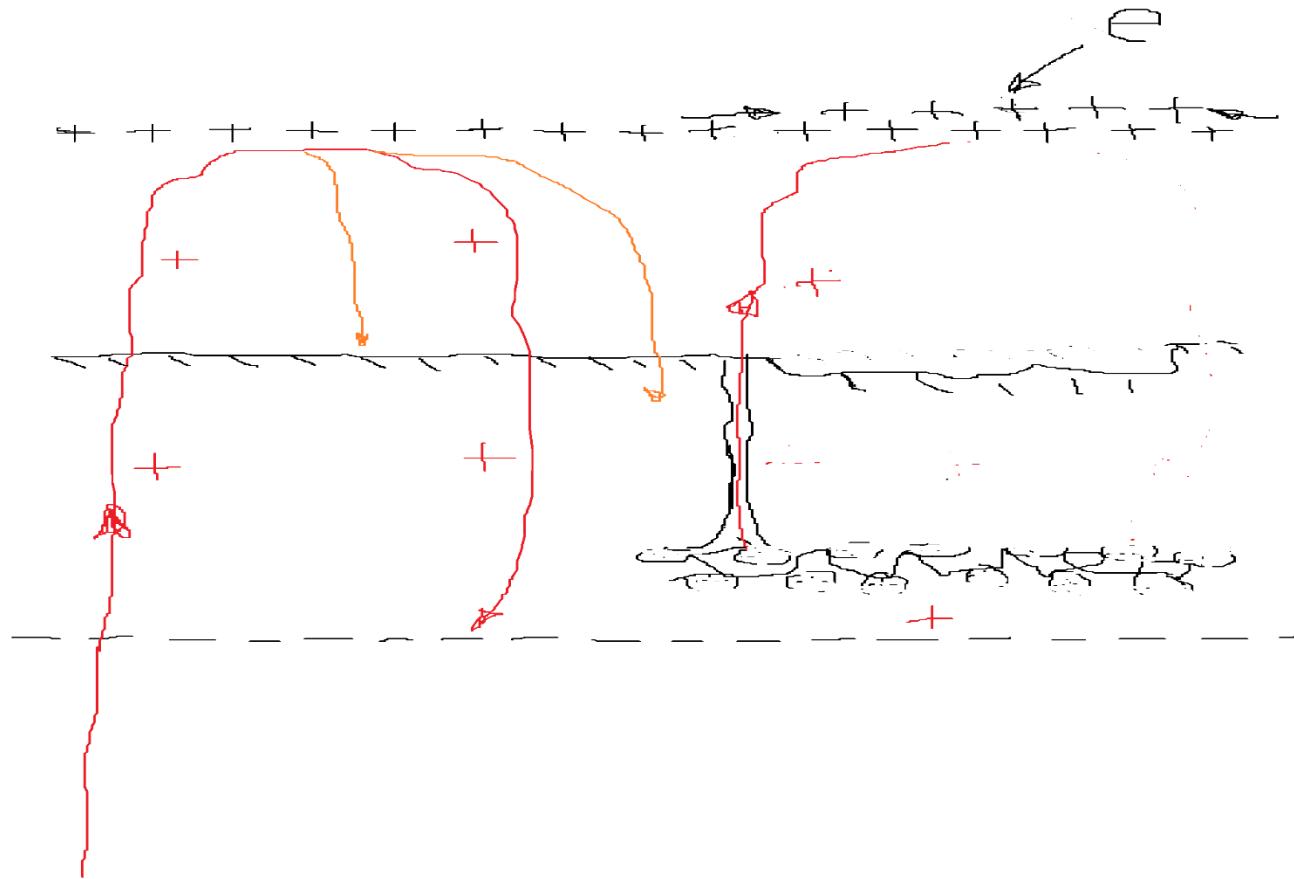

## 22 – 30 August 2008 year.

# Earthquake

- The rocks at the multi-kilometer depth are penetrated by multiple pores and broken by cracks. These pores are full of gases. Then gases escape from the pores and collapses.
- The gases are positively charged. So, the earthquake begins after gases escape from the pores and positive charge does not screen the negative located under crust.

# Summary

- The Hydride Earth model predicts the huge amount of K in the Earth.  $^{40}\text{K}$  geo antineutrino must contribute to Borexino single events. The suppression of CNO flux follows from Borexino results in this case. The reactions with fast alpha particles in the Sun can be the reason of such suppression.
- We developed the Hydride Earth Electricity (HEE) model. We prove the HEE experimentally. We observed the unusual predicted fact: The Earth crust (continents and ocean) saturates by positive ions (protons).

Examples of these areas were studied in Russia and Carolina in the US  
herein called the "Carolina Bays" (Fig. 1). The measured hydrogen fluxes are between 200 and 4400 m<sup>3</sup>/day/km<sup>2</sup> [Beaumont et al., 2015].

# Geology of hydrogen reservoirs

Hydrogen, having high calorific potential and being convertible to electricity and heat, is considered as an efficient energy carrier capable of transporting and storing energy [Panfilov, 2010]. The main application of hydrogen is the mobility sector, and it can also be injected into the natural gas grid. Large-scale hydrogen accumulations exist underground in the form of natural underground hydrogen reservoirs (UHR) in thermal aquifers.

UHR's have been discovered recently in all the parts of the world.
