

Primordial Nano BHs

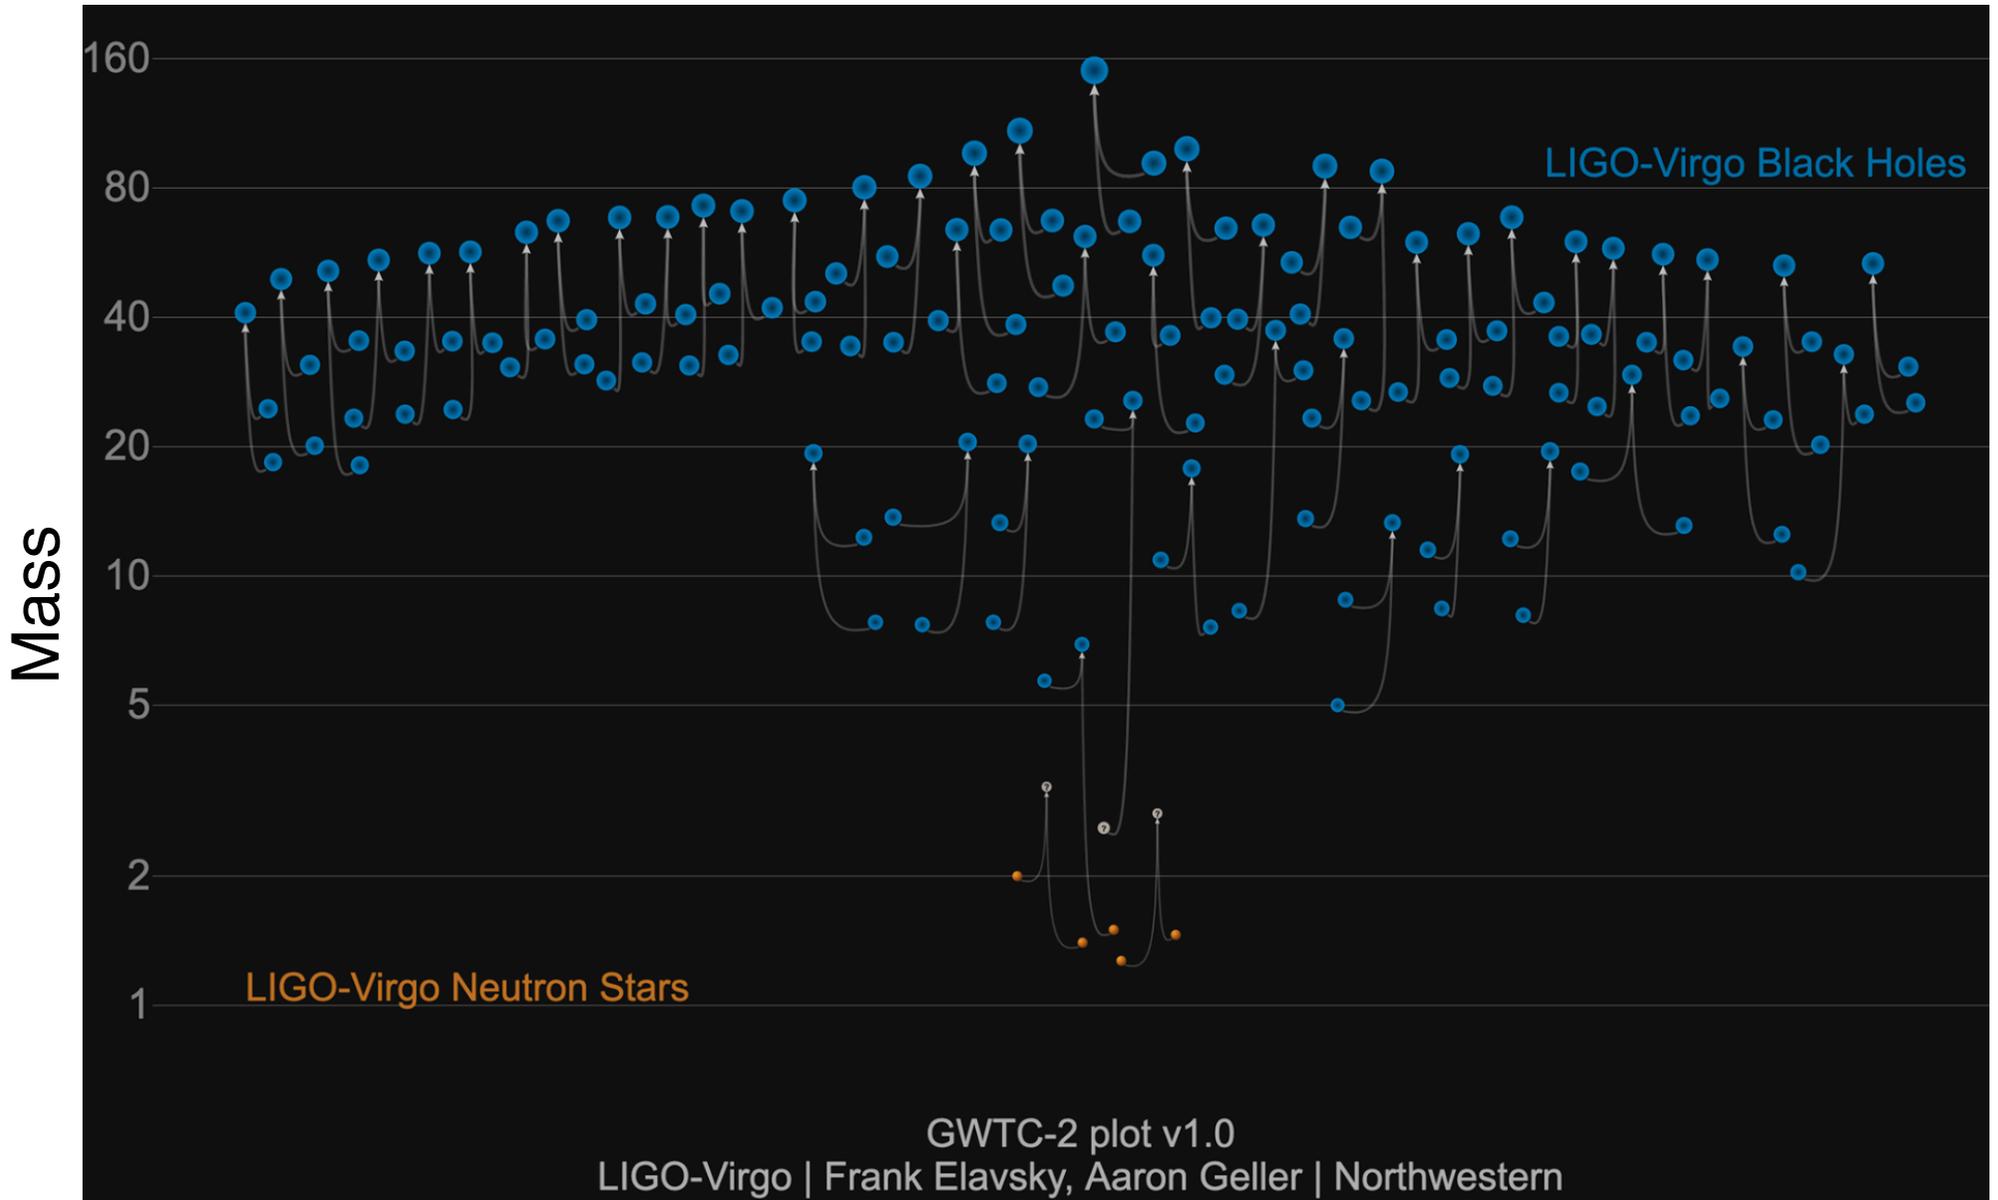

Antonio Riotto
University of Geneva

Plan of the talk

NANOGrav 12.5 yr signal consistent with the PBH scenario. If so, PBHs may comprise the totality of the dark matter

In collaboration with V. De Luca, G. Franciolini, PRL (2021)

Motivation

Black Holes

- Astrophysical BHs forms from the gravitational collapse of a star. We know they exist. Their mass must be above the Chandrasekhar limit,

$$M > \mathcal{O}(1) M_{\odot}$$

- PBHs are formed in the early universe. Their mass can be small and they can still be around as long as they do not evaporate within the age of the universe

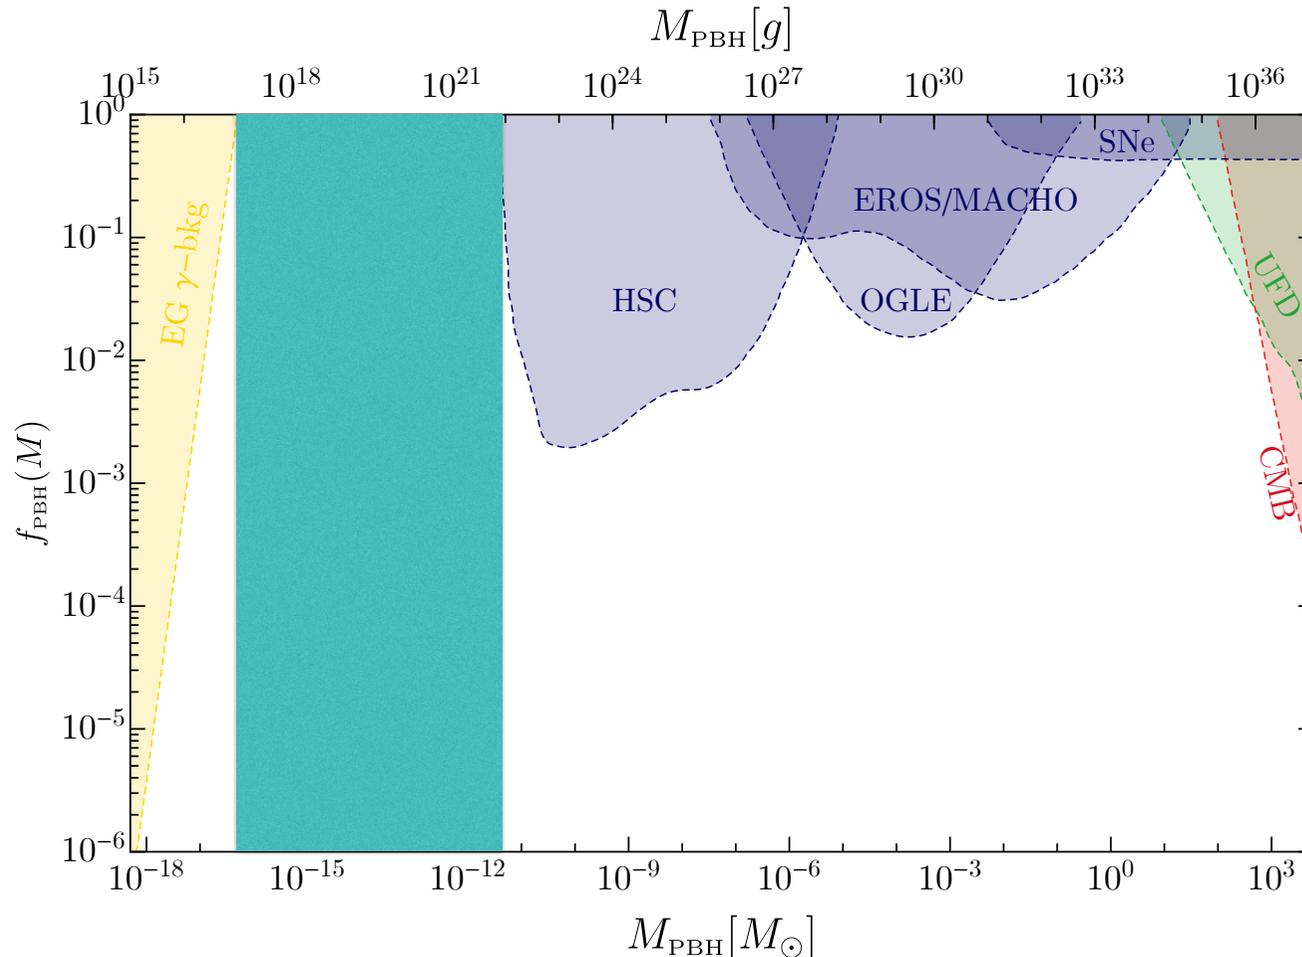

$$M > 10^{-18} M_{\odot}$$

- Can PBHs account for some of the LIGO/Virgo events?
- How to distinguish PBHs from astrophysical BHs?
- Can PBHs be the dark matter?

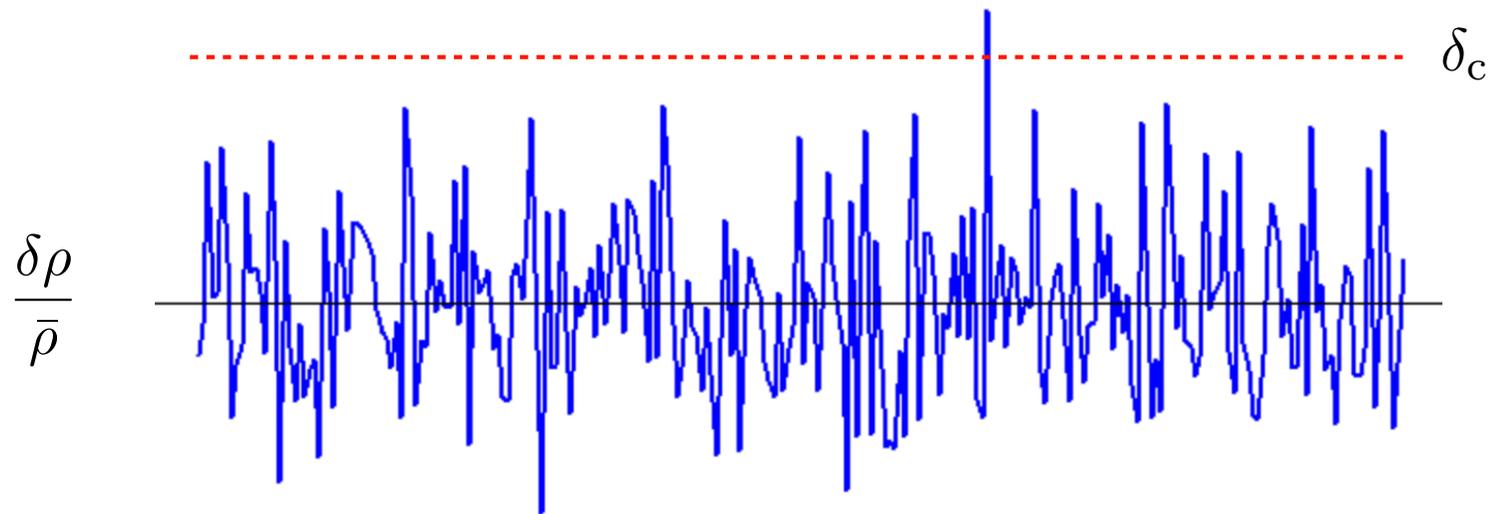

PBHs

Primordial black holes can compose all the dark matter (or a fraction of it)

$$f_{\text{PBH}} = \Omega_{\text{PBH}} / \Omega_{\text{DM}}$$

PBHs may be originated from peaks of the density contrast

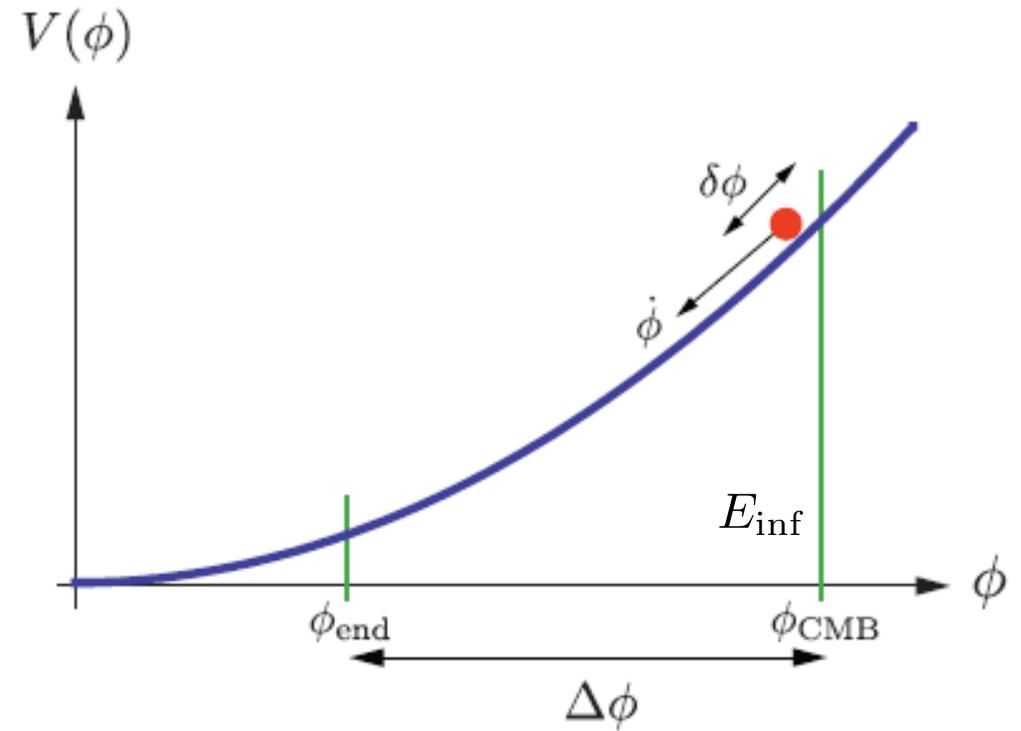

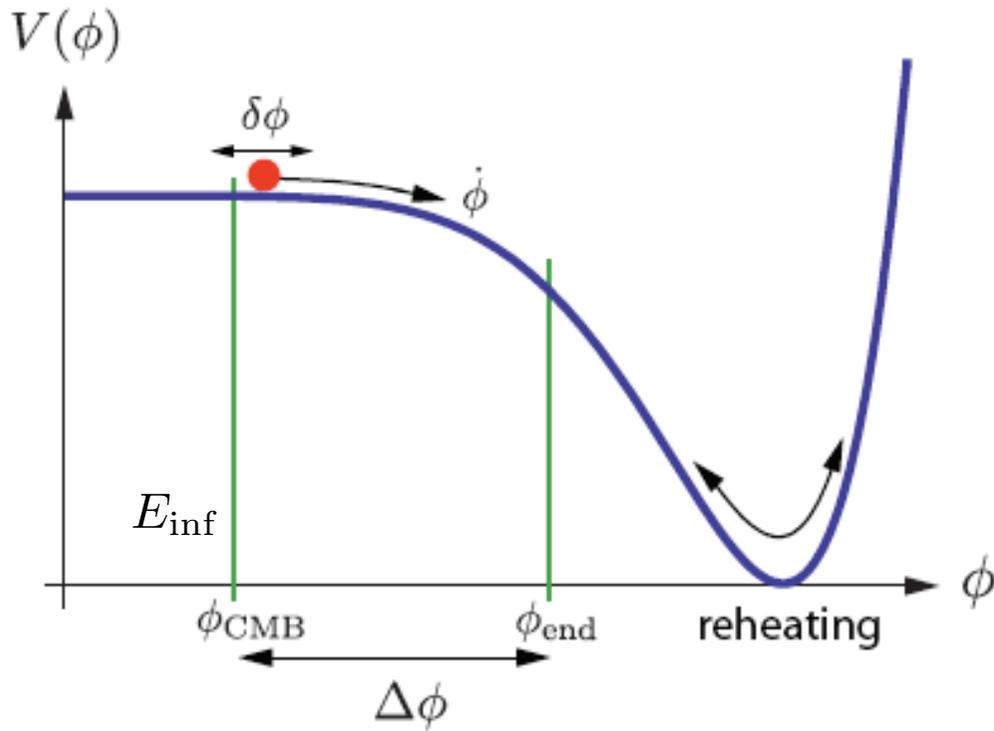

$$\frac{\delta\rho}{\bar{\rho}} \sim \frac{\nabla^2\zeta}{a^2 H^2}$$

PBHs are rare events, tail of the distribution

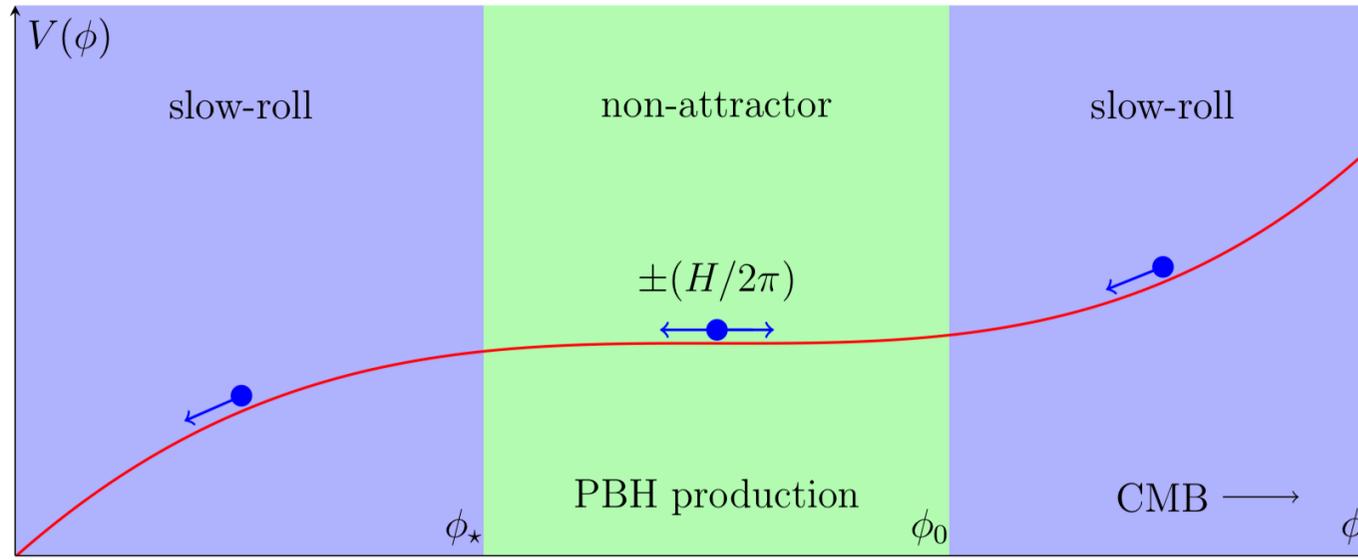

One possible mechanism: large fluctuations from inflation

Inflation

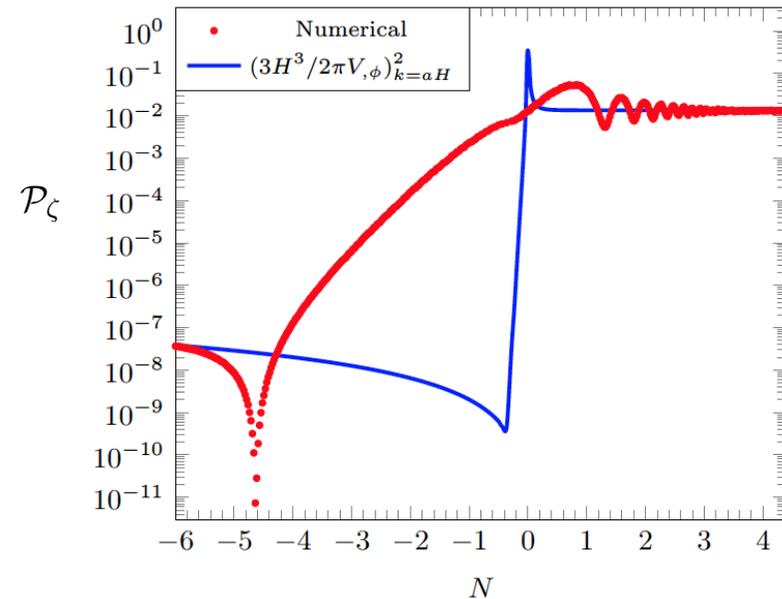

$$\left(\frac{\dot{a}}{a}\right)^2 = H^2 = \frac{\rho}{3m_{\text{P}}^2} = \frac{E_{\text{inf}}^4}{3m_{\text{P}}^2} \Rightarrow a(t) \sim e^{Ht}$$

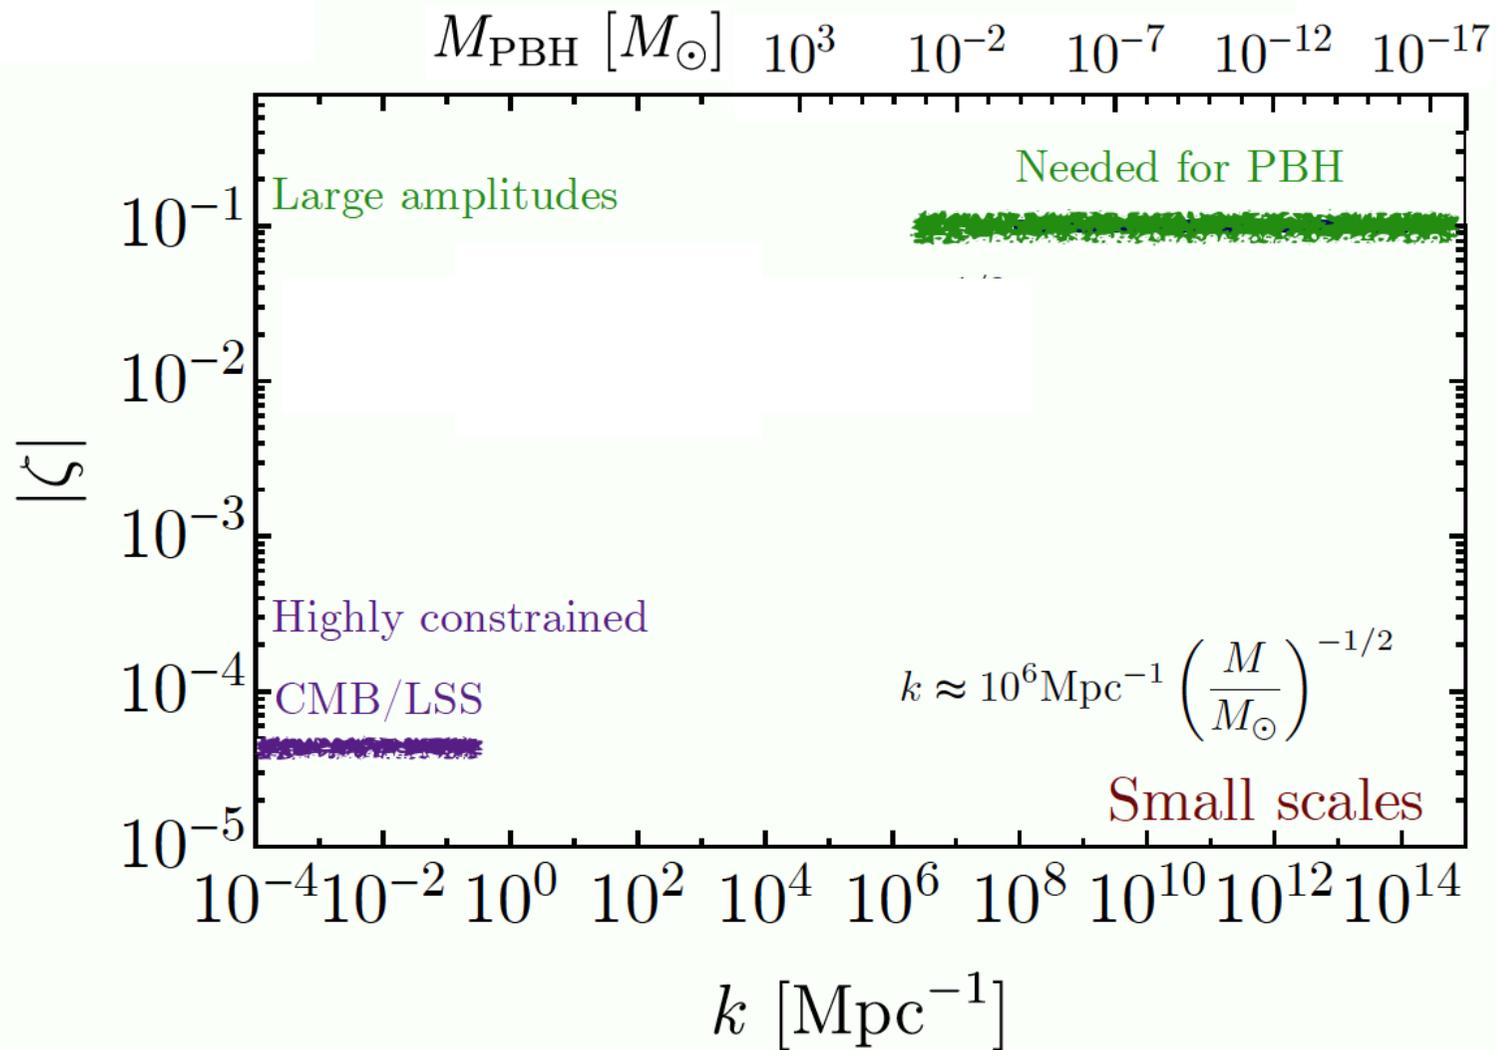

Ultra-slow-roll during inflation

$$\mathcal{P}_\zeta^{1/2} = \frac{H^2}{2\pi|\dot{\phi}|}$$

$$\frac{d\phi}{dN} \sim e^{-3N} \Rightarrow \mathcal{P}_\zeta^{1/2} \sim e^{3N}$$

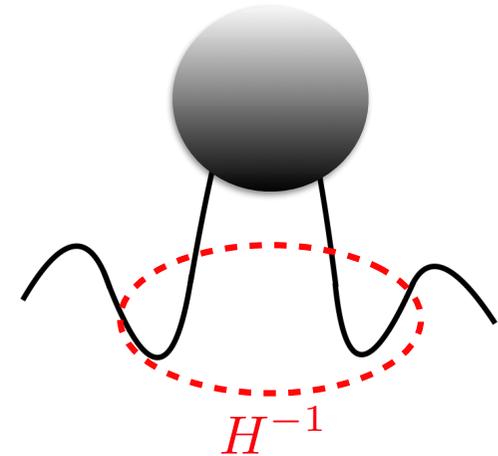

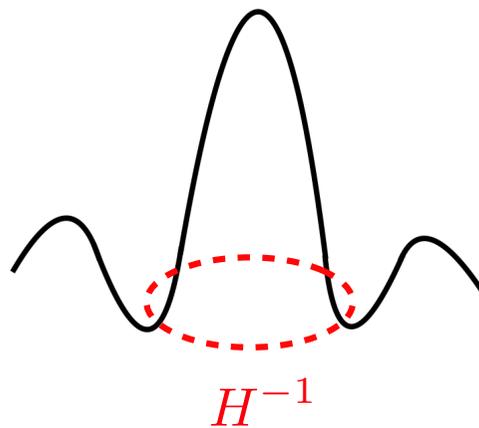

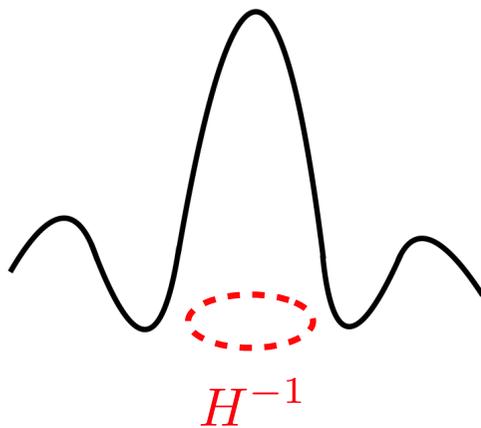

PBHs are originated from peaks of the density contrast

$$\frac{\delta\rho}{\rho} \gtrsim \delta_c$$

$$\frac{\delta\rho}{\bar{\rho}} \sim \frac{\nabla^2\zeta}{a^2 H^2}$$

$$M_{\text{PBH}} \sim M_{\text{H}}$$

$$\beta(M) = \int_{\delta_c}^{\infty} \frac{d\delta}{\sqrt{2\pi}\sigma_\delta} e^{-\delta^2/2\sigma_\delta^2} \quad \sigma_\delta^2 = \int_0^\infty d \ln k W^2(k, R_H) \mathcal{P}_\delta(k)$$

In fact, many non-Gaussian effects
in the threshold and in the non-linear mapping going from
the inflaton fluctuations to the curvature perturbation and to the density contrast

PBH formation probability

1.
$$\delta(r) = -\frac{8}{9} \left(\frac{1}{aH} \right)^2 e^{-5\zeta(r)/2} \nabla^2 e^{\zeta(r)/2}$$

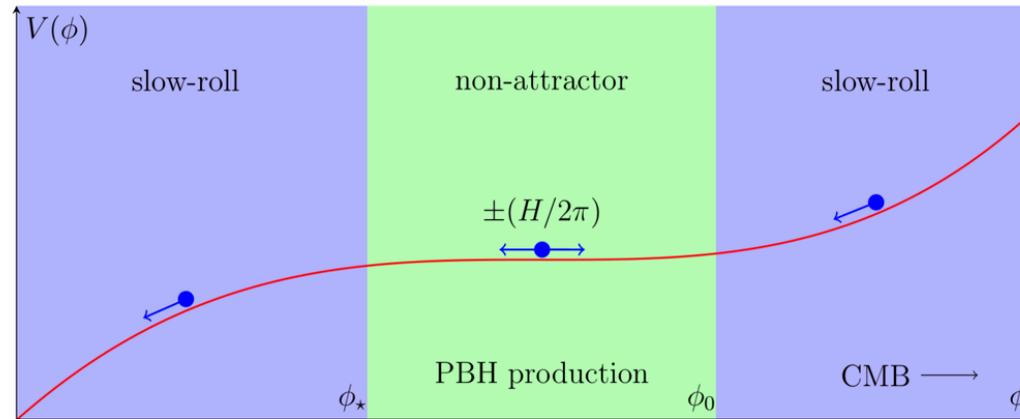

2.
$$\delta_m = \frac{3}{(r_m e^{\zeta(r_m)})^3} \int_0^{r_m} dr \delta(r) \left(r e^{\zeta(r)} \right)^2 \left(r e^{\zeta(r)} \right)'$$

3.
$$\delta_m = \delta_l - \frac{3}{8} \delta_l^2, \quad \delta_l = -\frac{4}{3} r_m \zeta'(r_m)$$

4.
$$P(\delta_m) d\delta_m = P(\delta_l) d\delta_l$$

PBH formation probability

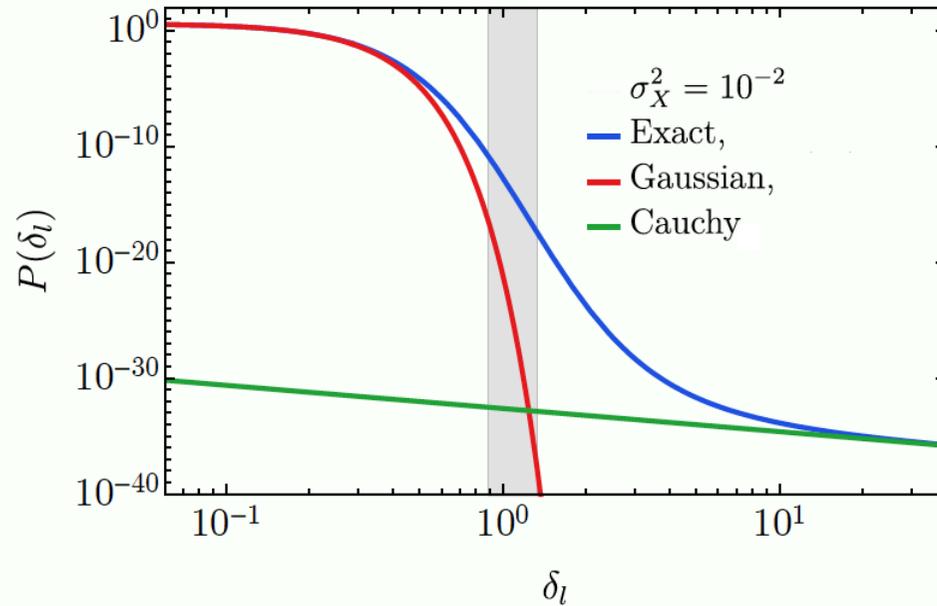

$$\phi''(N) + 3H\phi'(N) = 0 \quad \phi(N) = \phi_e + \frac{\pi_e}{3} (1 - e^{-3N})$$

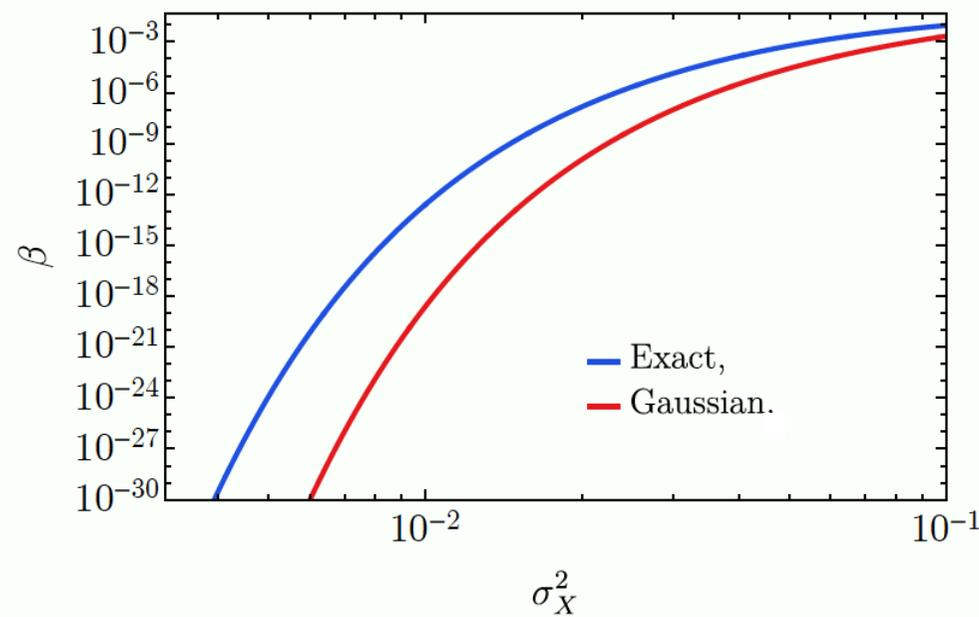

$$\zeta = -\delta N = -\frac{1}{3} \ln \left(1 + \frac{\delta\phi}{\bar{\pi}_e} \right)$$

$$\delta_l = -\frac{4}{3} r_m \zeta'(r_m) = \frac{4}{3} r_m \frac{\delta\phi'(r_m)/\bar{\pi}_e}{1 + 3\delta\phi(r_m)/\bar{\pi}_e}$$

PBH formation probability

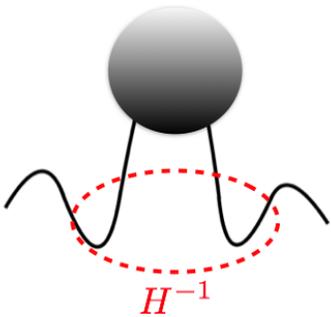

$$X = \frac{4}{3} r_m \delta \phi'(r_m) / \bar{\pi}_e$$

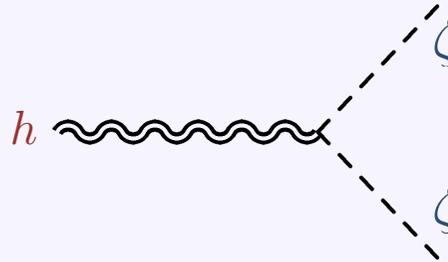

GWs from PBHs

The same curvature perturbations giving rise to PBHs are unavoidably a source for GWs at *second-order* in perturbation theory

$$\frac{\delta\rho}{\bar{\rho}} \sim \frac{\nabla^2\zeta}{a^2H^2}$$

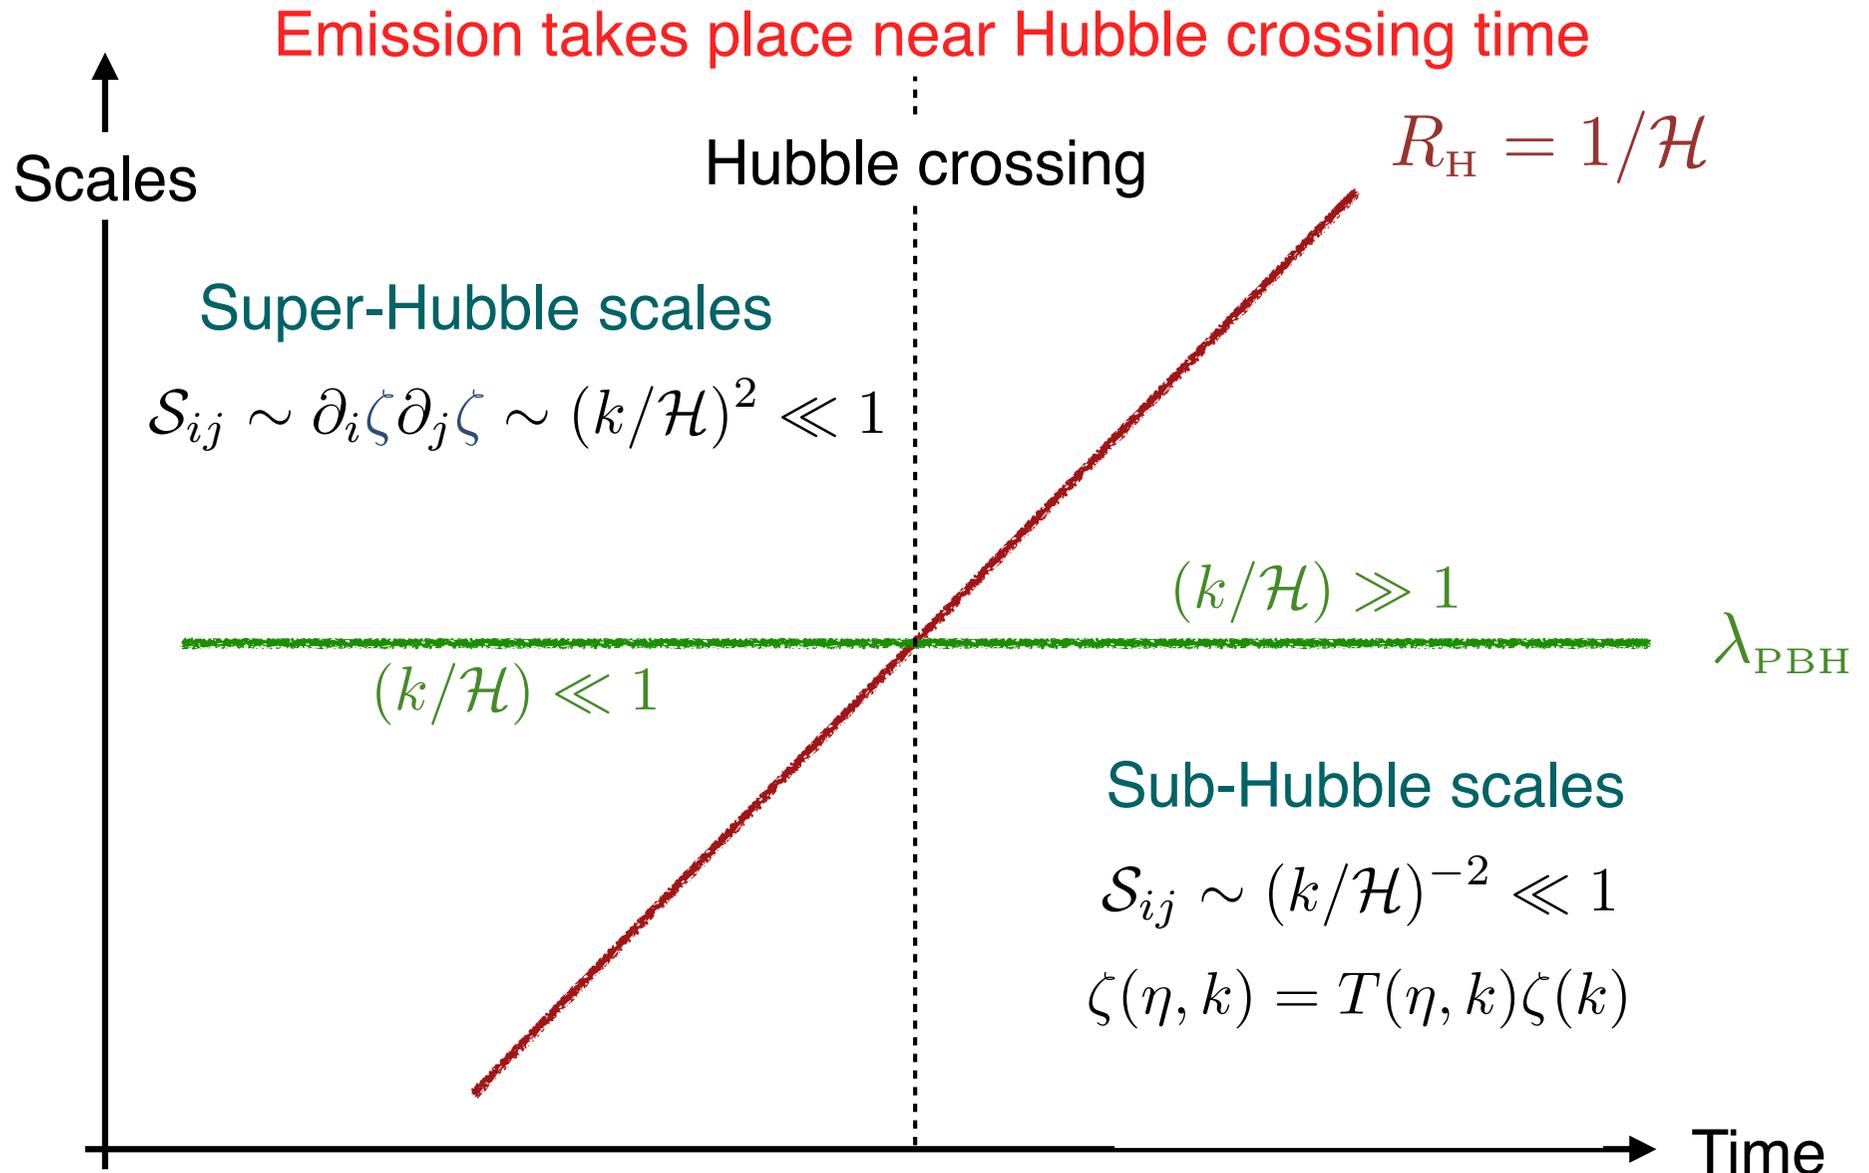

$$h''_{ij} + 2\mathcal{H}h'_{ij} - \nabla^2 h_{ij} = \mathcal{O}(\partial_i\zeta\partial_j\zeta)$$

Potentially observable at current and future GW observatories

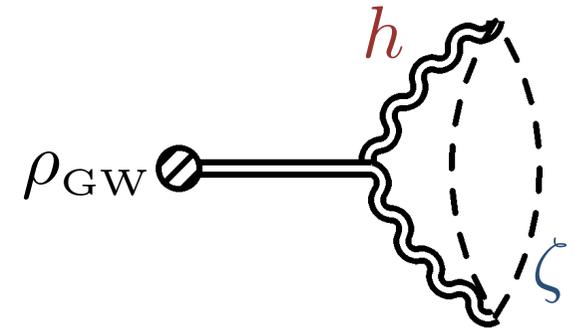

GWs from PBHs at second-order

GW abundance

The energy density of GWs is given by the time average over several cycles

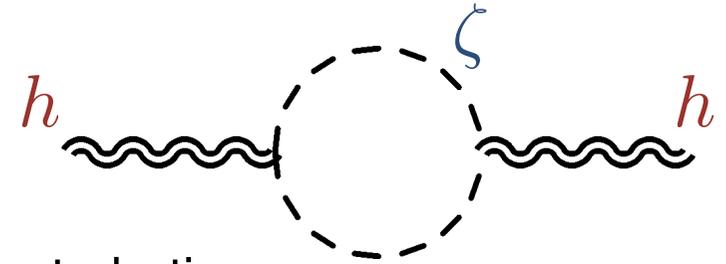

$$\Omega_{\text{GW}}(\eta, \vec{x}) = \frac{\rho_{\text{GW}}(\eta, \vec{x})}{\bar{\rho}(\eta)} = \frac{M_p^2}{4a^2 \bar{\rho}(\eta)} \langle h'_{ab}(\eta, \vec{x}) h'_{ab}(\eta, \vec{x}) \rangle_{\text{t.a.}}$$

GW Power Spectrum

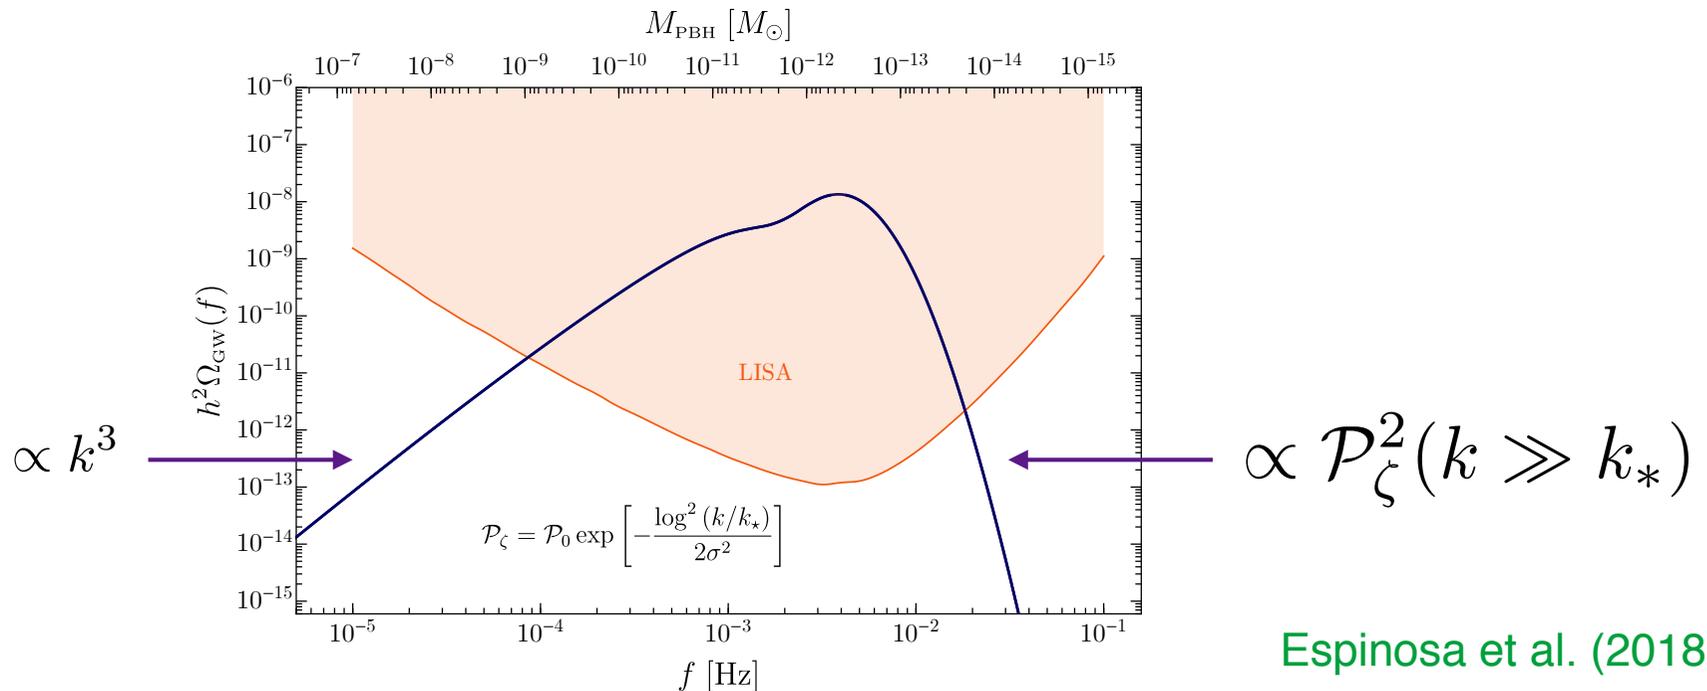

Power spectrum of GWs:

$$\left\langle h^{\lambda_1}(\eta, \vec{k}_1) h^{\lambda_2}(\eta, \vec{k}_2) \right\rangle' \approx \mathcal{P}_\zeta \mathcal{P}_\zeta$$

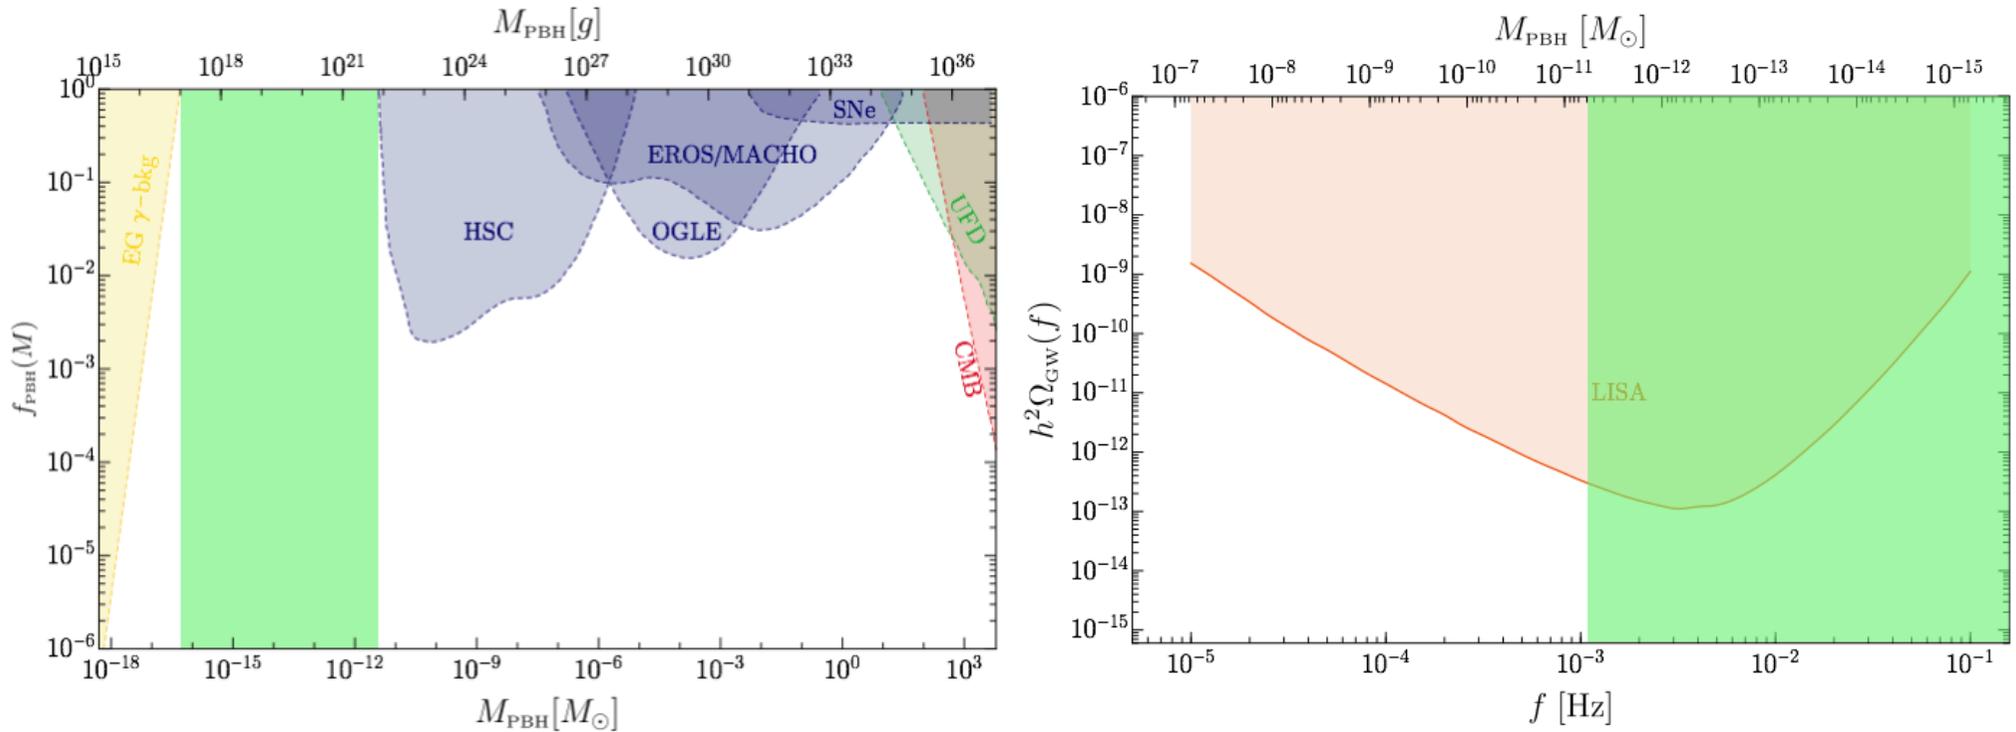

At second order in comoving curvature perturbation,
after averaging over the fast oscillating pieces

$$\Omega_{\text{GW}}(\eta, k) = \frac{\pi^2}{243\mathcal{H}^2\eta^2} \int \frac{d^3p}{(2\pi)^3} \frac{p^4 [1 - \mu^2]^2}{p^3 |\vec{k} - \vec{p}|^3} \mathcal{P}_\zeta(p) \mathcal{P}_\zeta(|\vec{k} - \vec{p}|) \mathcal{I}^2(\vec{k}, \vec{p})$$

The PBH dark matter-LISA serendipity

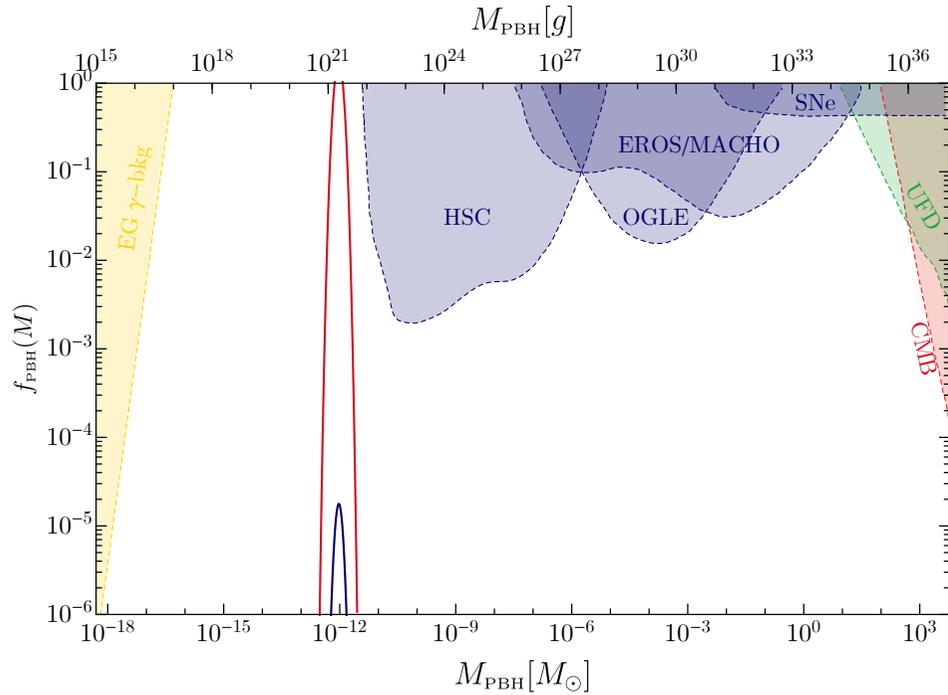

$$M \simeq 10^{-12} M_{\odot} \left(\frac{f_{\text{LISA}}}{f} \right)^2$$

$$f_{\text{LISA}} = 3.4 \text{ mHz}$$

$$M \approx 10^{-12} M_{\odot}$$

Bartolo et al. PRL (2019)

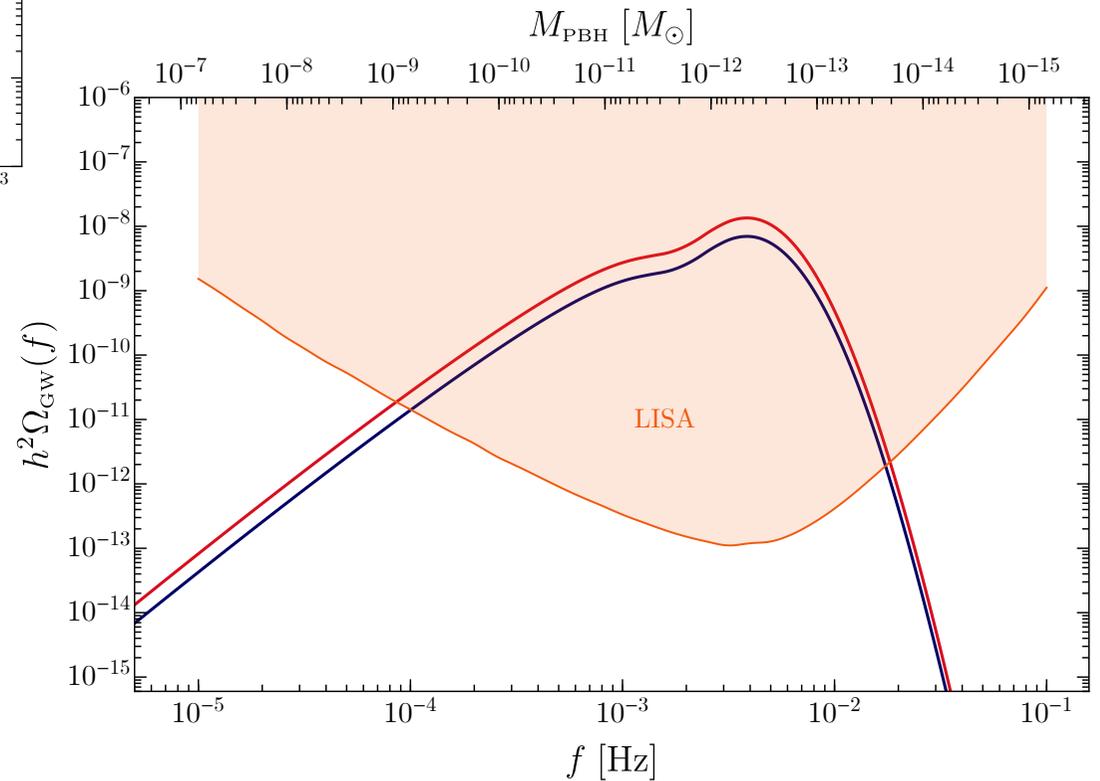

GWs even if PBHs not the DM

$$f_{\text{PBH}} \sim e^{-\delta_c^2 / 2\mathcal{A}^2}$$

$$\mathcal{P}_{\delta} \sim \mathcal{A}^2$$

$$\Omega_{\text{GW}} \sim \mathcal{A}^4$$

Nano-Grav 12.5 year

Millisecond pulsars whose signal sensitive to the stochastic GW background

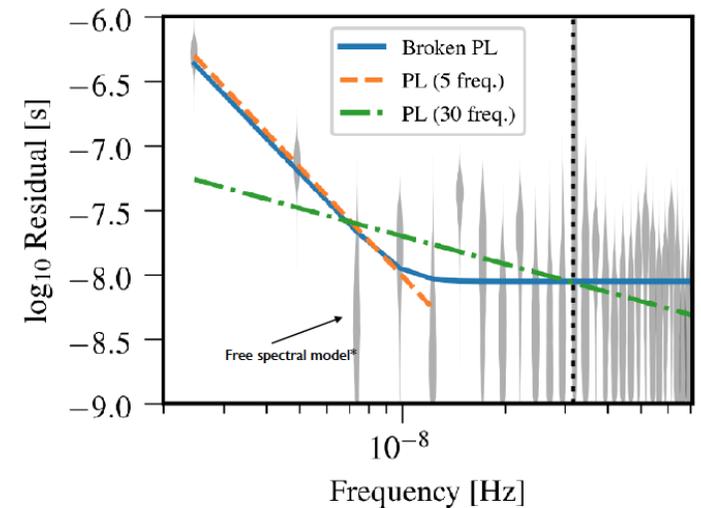

Cross-correlation of
timing residuals

$$S_{ab} = \Gamma_{ab} \frac{h_c^2}{12\pi^2 f^3}$$

Nano-Grav 12.5 year

Strong evidence for a stochastic common process across 45 pulsars

$$\Omega(f) = \frac{2\pi^2}{3H_0^2} A^2 f_{\text{yr}}^2 \left(\frac{f}{f_{\text{yr}}} \right)^{5-\gamma}$$

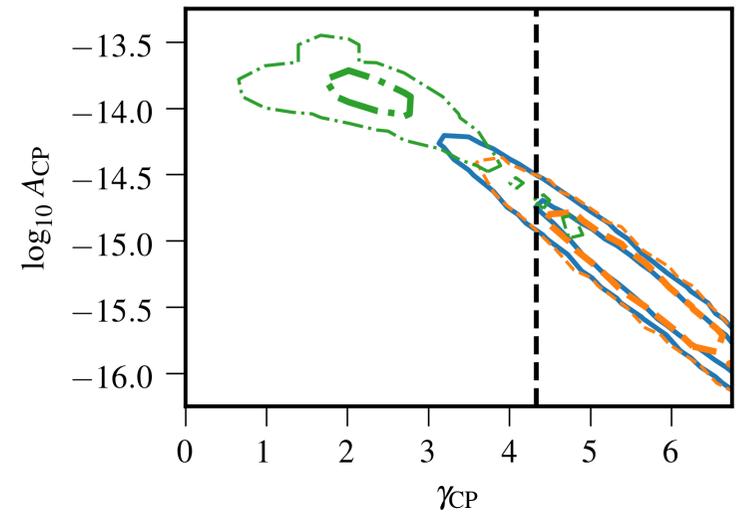

Possible flat spectrum with amplitude

$$\Omega(f) \sim 5 \cdot 10^{-10}$$

Nano-Grav 12.5 year

Strong evidence for a stochastic common process across 45 pulsars

$$\Omega(f) = \frac{2\pi^2}{3H_0^2} A^2 f_{\text{yr}}^2 \left(\frac{f}{f_{\text{yr}}} \right)^{5-\gamma}$$

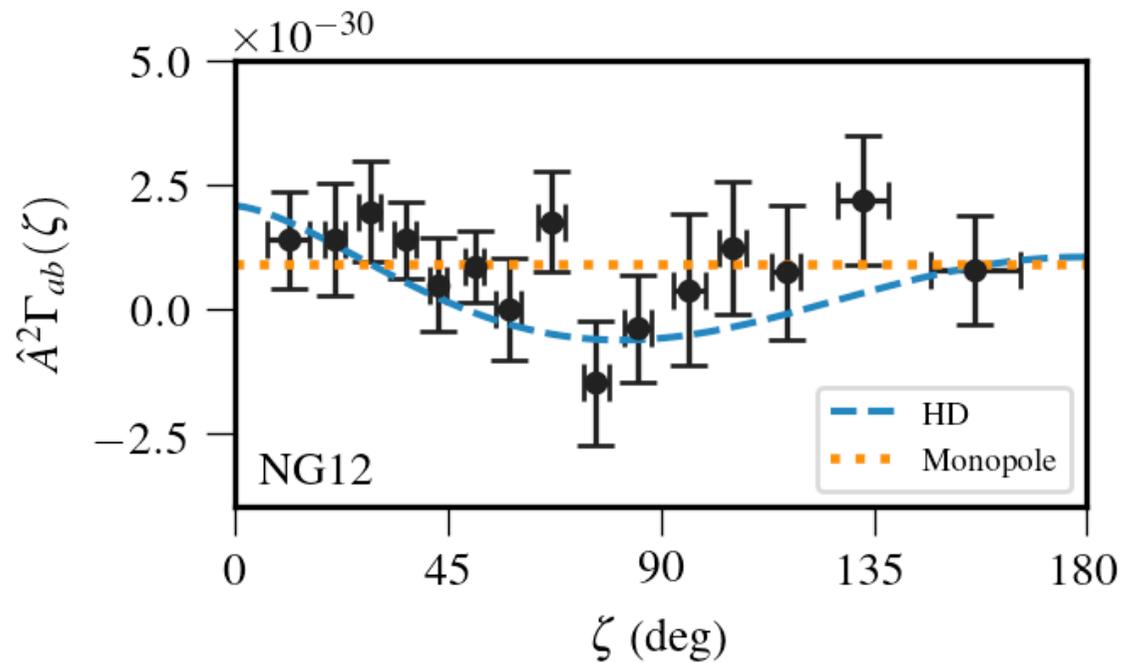

Possible flat spectrum with amplitude

$$\Omega(f) \sim 5 \cdot 10^{-10}$$

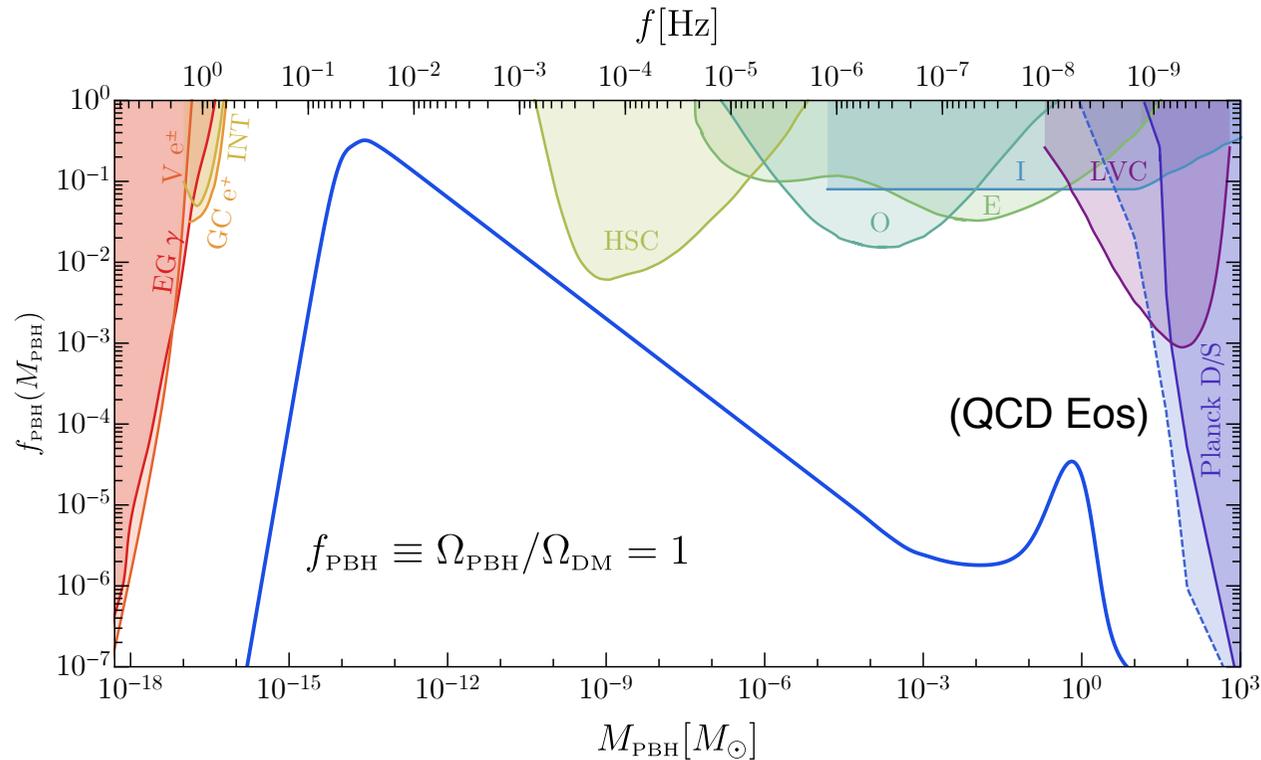

Nano-Grav 12.5 year

Non-conclusive evidence for quadrupolar Hellings-Downs (HD) correlation pattern (GW footprint)

Need to wait for more data (two years on)

Can be consistent with a PBH = DM scenario

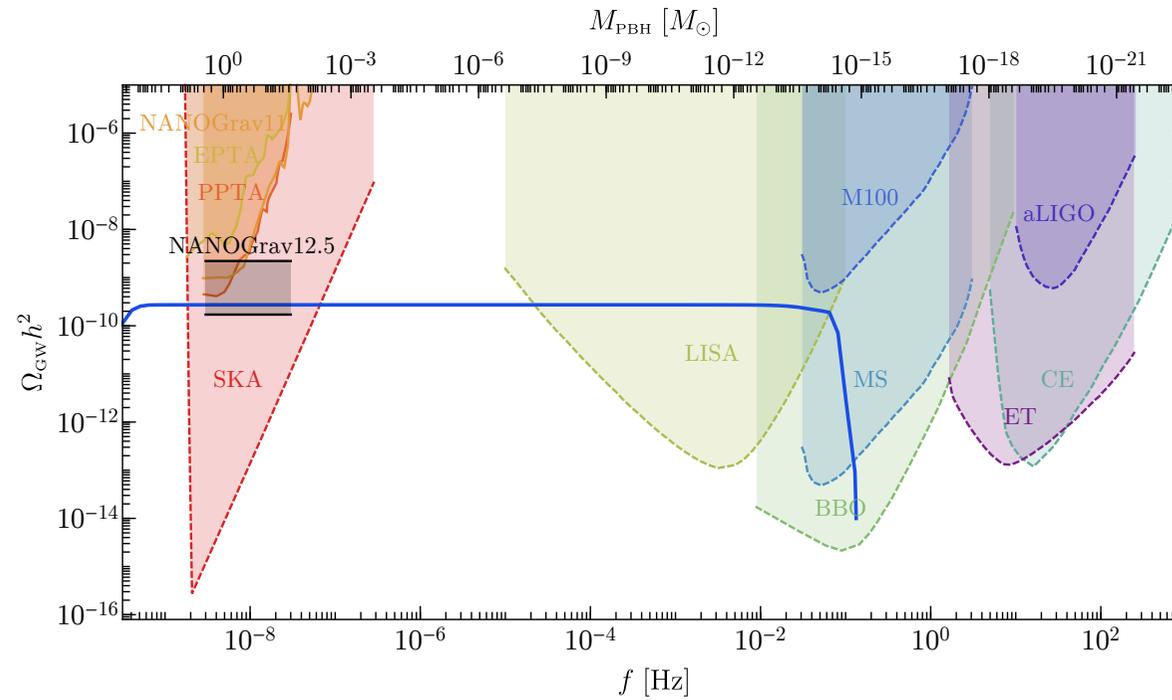

From flat curvature power spectrum

$$\mathcal{P}_{\zeta}(k) = A_{\zeta} \Theta(k_s - k) \Theta(k - k_l) \quad k_s \gg k_l$$

PBH mass peaked at the shortest scale

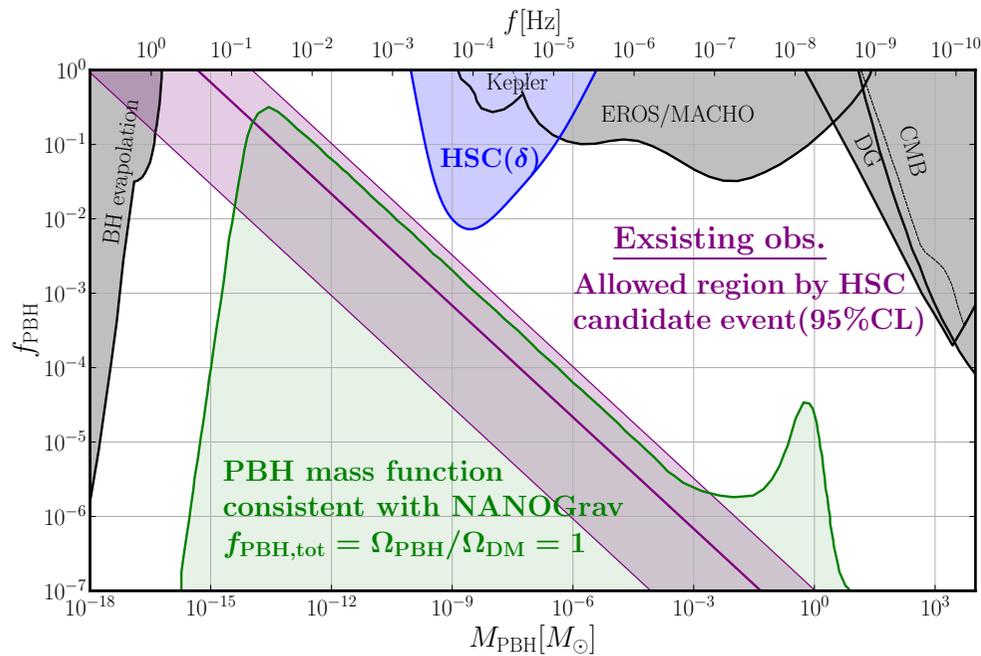

Can be consistent with a PBH = DM scenario

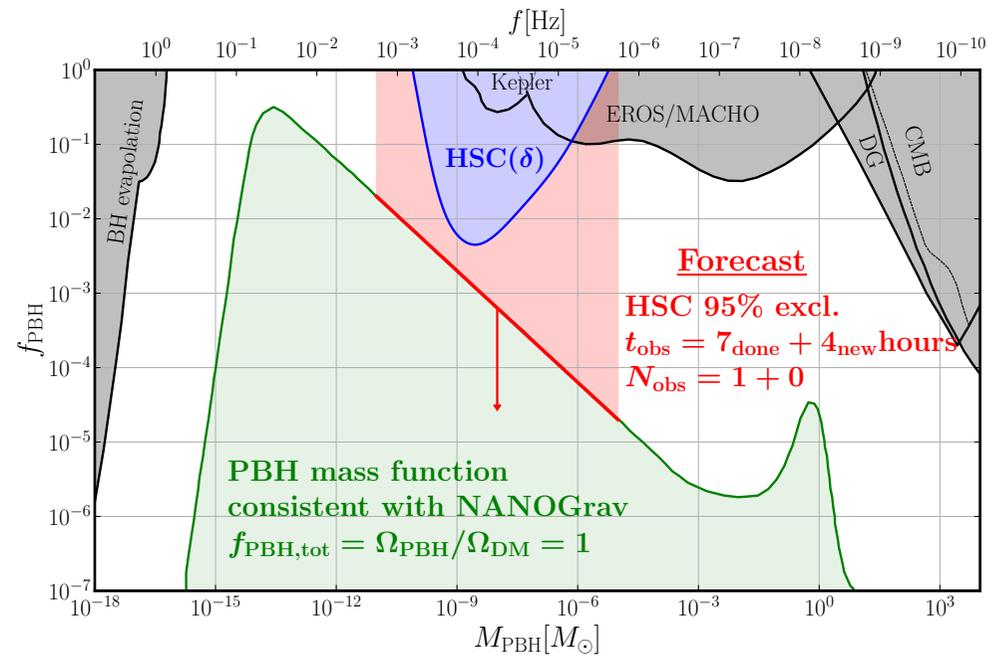

May be confirmed by LISA

Can be consistent with the HSC event

Hyper-Supreme Camera searches for microlensing
of light from the Andromeda galaxy (M31)

Allowed region allowed assuming
a power-law mass function

Forecast with longer
observation time assuming null detection

Conclusions

NANOGrav 12.5 yr signal consistent with the PBH scenario.

If so, PBHs may comprise the totality of the dark matter.
